

Day 06 - Linux Mock Interview Revision

Q1: Website Down

Flow: SSH → curl localhost:PORT → systemctl status → ss -tulpn → top/free -h/df -h → journalctl → application logs → identify root cause → fix → verify.

Q2: curl localhost:3000 = Connection refused

Application is not accepting connections. Check systemctl status, ss -tulpn, journalctl and application logs.

Q3: CPU 98%

Do NOT kill the process immediately. Use top and ps aux --sort=-%cpu, investigate the process, logs and root cause first.

Q4: Permission Problem

Use whoami → id → ls -l → systemctl status → journalctl → fix using chmod/chown if required.

Rapid Fire

ps aux = snapshot, top = live processes
chmod = permissions, chown = ownership
df = filesystem usage, du = directory usage
ping = machine reachability, curl = application response
tail = last lines, tail -f = live logs
cat = full file, less = paginated view
kill -15 = graceful, kill -9 = force kill
whoami = current user, id = user/group IDs
journalctl = systemd logs
ss -tulpn = listening ports & processes

Golden Workflow

Investigate → Collect Evidence → Root Cause → Fix → Verify → Prevent

Six Commands

systemctl status, curl localhost:PORT, ss -tulpn, top, free -h, journalctl
